Universal Codes, V2V Codes, and Shannon-Fano-Elias Codes
Last Lecture: Entropy Measures

Entropy Measures

- Scalar/marginal entropy:
  \[ H(S_n) = \mathbb{E}\{-\log_2 p(S_n)\} \]

- Conditional entropy:
  \[ H(S_n | S_{n-1}) = \mathbb{E}\{-\log_2 p(S_n | S_{n-1})\} \]

- \(N\)-th order block entropy:
  \[ H_N(S) = H(S_n, \ldots, S_{n+N-1}) = \mathbb{E}\{-\log_2 p(S_n, \ldots, S_{n+N-1})\} \]

Important Relations for Entropy Measures

- Conditioning never increases entropy:
  \[ H(S_n | S_{n-1}, S_{n-2}) \leq H(S_n | S_{n-1}) \leq H(S_n) \]

- Increasing block size never increases lower bound:
  \[ \frac{1}{N} H_N(S) \leq \frac{1}{N-1} H_{N-1}(S) \leq H(S_n) \]

Entropy Rate and Relations for Stationary Sources

- Entropy rate \(\bar{H}(S)\)
  \[ \bar{H}(S) = \lim_{N \to \infty} \frac{1}{N} H_N(S) \]

  with

  \[ \bar{H}(S) \leq H(S_n) \quad \text{(equality iff } S \text{ is iid)} \]

  \[ \bar{H}(S) \leq \frac{1}{N} H_N(S) \quad \text{(equality iff } S \text{ is iid)} \]

  \[ \bar{H}(S) \leq H(S_n | S_{n-1}) \quad \text{(equality iff } S \text{ is Markov)} \]
Last Lecture: Huffman Codes

Types of Variable-Length Codes

- Scalar codes: Assign one codeword to each possible symbol
- Blocks codes: Assign one codeword to each possible block of $N$ successive symbols
- Conditional codes: Multiple scalar codeword tables: Table for current symbol $s_n$ is selected based on the value of a condition $c_n = f(s_{n-1}, \cdots)$

Huffman Algorithm

- Generates one optimal prefix code (minimum redundancy) for any given finite pmf
- Can be used for all types of variable-length codes: scalar, conditional, block codes, etc.

Bounds on Average Codeword Length (note: lower bound applies to all codes of a type)

- Scalar Huffman codes: $H(S_n) \leq \bar{\ell} < H(S_n) + 1$
- Block Huffman codes of size $N$: $\frac{1}{N} H_N(S) \leq \bar{\ell} < \frac{1}{N} H_N(S) + \frac{1}{N}$
- Conditional Huffman codes: $H(S_n | C) \leq \bar{\ell} < H(S_n | C) + 1$ with $C = f(S_{n-1}, S_{n-2}, \cdots)$
- All lossless codes: $\bar{H}(S) \leq \bar{\ell}$
Unary Code

- **Structured code** for non-negative integers $n$
- Very simple encoding and decoding
- Optimal for geometric pmf $p(n) = p(1 - p)^n$ with $p = 0.5$

</tbody>
</table>

**// encoding**

```c
void encExpGolomb ( int n, int k )
{
    // good implementation for first line
    // should be based on finding the
    // most significant bit in an integer
    int p = floor( log2( n+(1<<k)) ) - k;
    int m = (1 << (k+p)) - (1<<k);
    encUnary ( p );
    encFixed( n-m, k+p ); // k+p bits
};
```

**// decoding**

```c
int decExpGolomb ( int k )
{
    int p = decUnary();
    int s = decFixed( k+p );
    int m = (1 << (k+p)) - (1<<k);
    return m+s;
};
```

- **Exp-Golomb order 0 used in:**
  - H.264 | AVC
  - H.265 | HEVC, VVC
V2V Codes

Generalization of Block Codes

- Assign variable-length codewords to symbol sequences of variable-length \((V2V)\)
- How to select symbol sequences?
  - All messages must be representable by symbol sequences
  - Desirable: Redundancy-free set of symbol sequences

Examples: Binary symbol alphabet \(A = \{a, b\}\)

<table>
<thead>
<tr>
<th>code A</th>
<th>code B</th>
<th>code C</th>
<th>code D</th>
</tr>
</thead>
<tbody>
<tr>
<td>aaaa</td>
<td>aaa</td>
<td>aaaa</td>
<td>aa</td>
</tr>
<tr>
<td>aaab</td>
<td>aa</td>
<td>aaab</td>
<td>ab</td>
</tr>
<tr>
<td>aab</td>
<td>a</td>
<td>aab</td>
<td>ba</td>
</tr>
<tr>
<td>bba</td>
<td>b</td>
<td>bba</td>
<td>bba</td>
</tr>
<tr>
<td>ba</td>
<td>bb</td>
<td>b</td>
<td>bbb</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1</td>
</tr>
</tbody>
</table>

| abbbb... ? | redundant! | suitable | suitable |

Heiko Schwarz (Freie Universität Berlin) — Data Compression: Universal Codes, V2V Codes, and Shannon-Fano-Elias Codes
Suitable Sets of Symbol Sequences?

- Consider \( m \)-ary alphabet \( \mathcal{A} = \{a_1, a_2, \cdots, a_m\} \)

- **All sets of symbol sequences that are representable by a full \( m \)-ary tree**
  - All messages are representable by a concatenation of the individual symbol sequences
  - Note: Fill symbol sequence at end of message (as for block codes)
  - Redundancy-free set of symbol sequences
  - Instantaneous encodable codes

Special Cases

- **Scalar code:** Full \( m \)-ary tree of depth 1
- **Block code of size \( N \):** Perfect \( m \)-ary tree of depth \( N \)

**Example: Ternary alphabet**

\[
\begin{align*}
\text{aaa} & \leftrightarrow 1 \\
\text{aab} & \leftrightarrow 000 \\
\text{aac} & \leftrightarrow 01000 \\
\text{ab} & \leftrightarrow 001 \\
\text{ac} & \leftrightarrow 01001 \\
\text{b} & \leftrightarrow 011 \\
\text{c} & \leftrightarrow 0101
\end{align*}
\]

\[
\mathcal{A} = \{a, b, c\} \quad \Rightarrow \quad m = 3
\]
Prefix Codes for Symbol Sequences: V2V Codes as Double Tree

**iid source (m = 3)**

<table>
<thead>
<tr>
<th>symbol</th>
<th>probability</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>0.80</td>
</tr>
<tr>
<td>b</td>
<td>0.15</td>
</tr>
<tr>
<td>c</td>
<td>0.05</td>
</tr>
</tbody>
</table>

**entropy rate:** \( \bar{H}(S) = 0.88418 \) (equal to \( H(S) \))

**scalar Huffman:** \( \bar{\ell} = 1.2 \) (3 codewords)

**2-symbol blocks:** \( \bar{\ell} = 0.93375 \) (9 codewords)

**V2V code:** \( \bar{\ell} = 0.88934 \) (7 codewords)

\( \varrho = 0.00516 \) (0.58%)
Average Codeword Length of V2V Codes

What we know

- Structure of V2V code:
  - $N$: number of symbol sequences (leaf nodes)
  - $n_k$: number of symbols in $k$-th symbol sequence
  - $\ell_k$: length of codeword for $k$-th symbol sequence

- Statistical properties of source:
  - $p_k$: probability of $k$-th symbol sequence

Average Codeword Length of V2V Codes

$$\bar{\ell} = \frac{\text{average codeword length per sequence}}{\text{average number of symbols per sequence}} = \frac{\sum_{k=1}^{N} p_k \cdot \ell_k}{\sum_{k=1}^{N} p_k \cdot n_k}$$
How to Determine the PMF for Symbol Sequences?

How can we determine the pmf $p(a_k)$ for the selected symbol sequences $a_k = (a_{k1}, a_{k2}, \ldots, a_{kn})$?

**IID Sources**
- No dependencies on previous symbols $\Rightarrow p(a_k) = p(a_{k1}) \cdot p(a_{k2}) \cdot \ldots \cdot p(a_{kn})$

**General Stationary Sources**
- Probability that a symbol sequence starts with any particular letter depends on preceding symbols
- Probabilities $p(a_k)$ of symbol sequences $a_k$ can be determined by solving linear equation system
- Further details can be found in [Wiegand, Schwarz: “Source Coding”]

**In Practice: Estimate Pmf based on Training Set**
- Use (large) training set of typical messages for the considered source
- Count occurrences $N(a_k)$ of variable-length symbol sequences $a_k$ in the messages of the training set
- Estimate probability $p(a_k)$ according to
  $$p(a_k) = \frac{N(a_k)}{\sum_k N(a_k)}$$
Optimal V2V Codes for Given Set of Symbol Sequence

What is given?
- Set of \( N \) variable-length symbol sequences \( a_k \) with \( n_k \) symbols
- Associated probabilities masses \( p_k = P(S_{\text{next}} = a_k) \)

Optimal V2V Codes
- Assign codewords of length \( \ell_k \) to symbol sequences \( a_k \)
- Goal: Minimize average codeword length per symbol

\[
\bar{\ell} = \frac{\bar{\ell}_{\text{seq}}}{\bar{n}} = \frac{\sum_{k=1}^{N} p_k \ell_k}{\sum_{k=1}^{N} p_k n_k} \quad \leftarrow \text{optimization problem: best prefix code for given pmf } \{p_k\}
\]

\( \bar{n} \) — fixed value for given set \( \{a_k\} \) and given pmf \( \{p_k\} \)

\( \rightarrow \) **Optimal code can be obtained by Huffman algorithm for pmf \( \{p_k\} \)**

\( \rightarrow \) Resulting average codeword length per symbol is bounded by

\[
\left( \frac{-\sum_{k=1}^{N} p_k \log_2 p_k}{\sum_{k=1}^{N} p_k n_k} \right) \leq \bar{\ell} < \left( \frac{-\sum_{k=1}^{N} p_k \log_2 p_k}{\sum_{k=1}^{N} p_k n_k} \right) + \left( \frac{1}{\sum_{k=1}^{N} p_k n_k} \right)
\]
**Example: Coding of Black and White Document Scans (300 dpi)**

**Code design:**
- Select set of symbol sequences \( a_k \) (full \( m \)-ary tree)
- Experimentally determine pmf \( p_k = p(a_k) \) using actual document scans
- Apply Huffman algorithm for determining codewords

### block Huffman code

\]

\( \bar{n} = 5.516 \)

**→ V2V code is better than block Huffman code with same table size (36% bit savings)**
Optimal V2V Codes for Given Maximum Table Size

Optimal Code for Maximum Number $N$ of Codewords?

- No known design algorithm
- Exhaustive search over all possible full $m$-ary trees with up to $N$ leaf nodes
- Extremely complex

Example: Stationary Markov Source

<table>
<thead>
<tr>
<th>alphabet $\mathcal{A} = {a, b, c}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$x$</td>
</tr>
<tr>
<td>---</td>
</tr>
<tr>
<td>$a$</td>
</tr>
<tr>
<td>$b$</td>
</tr>
<tr>
<td>$c$</td>
</tr>
</tbody>
</table>

Entropy rate $\tilde{H} = 0.7331$

<table>
<thead>
<tr>
<th>optimal codes: $\tilde{\ell}$ for selected table sizes $N$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$N$</td>
</tr>
<tr>
<td>---</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>9</td>
</tr>
<tr>
<td>13</td>
</tr>
<tr>
<td>17</td>
</tr>
<tr>
<td>21</td>
</tr>
<tr>
<td>27</td>
</tr>
<tr>
<td>81</td>
</tr>
</tbody>
</table>
**V2V Codes in Practice**

**Only Structured V2V Codes**
- Set of symbol sequences follow a certain structure
- Examples:
  - run-length coding
  - run-level coding

<table>
<thead>
<tr>
<th>Run-length Coding</th>
<th>Run-level Coding</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type 1</td>
<td>Type 2</td>

</tbody>
</table>

(x: max. value)
Run-Level Coding (JPEG, MPEG-2 Video, ...)

4, 0, 0, 1, 0, 1, 0, 1, 0, 0, 0

Coding of Block Quantization Indexes (absolute values)

1. Convert block into sequence of indexes (zig-zag scan)
2. Convert sequence of indexes into (run, level) pairs and a special end-of-block (eob) symbol
   - run: number of zeros that precede next non-zero index
   - level: value of next non-zero index
   - eob: all following indexes are equal to zero (end-of-block)

Example: sequence of indexes: 4 0 0 1 0 1 0 0 ··· 0
   (run, level) pairs: (0, 4) (2, 1) (1, 1) (eob)

3. Codewords are assigned to (run, level) pairs

MPEG-2 Video: 112 typical symbol sequences + escape

Shannon-Fano-Elias Coding and Arithmetic Coding

Our Findings

- Achievable coding efficiency is limited by entropy rate: $\bar{\ell} \geq \bar{H}$
- Block Huffman codes approach entropy rate $\bar{H}$ for large block sizes $N$

$$\left( \frac{1}{N} H_N \right) \leq \bar{\ell} < \left( \frac{1}{N} H_N \right) + \left( \frac{1}{N} \right), \quad \bar{H} = \lim_{N \to \infty} \frac{1}{N} H_N$$

Not implementable due to extreme memory requirements for large $N$

Basic Idea of Arithmetic Coding

- Block codes for large $N$ stay efficient even if they are slightly suboptimal, e.g.,

$$\left( \frac{1}{N} H_N \right) + \left( \frac{A}{N} \right) \leq \bar{\ell} < \left( \frac{1}{N} H_N \right) + \left( \frac{1 + A}{N} \right) \quad \text{with} \quad A \ll N$$

- If accepting suboptimality, can we construct codewords on-the-fly (i.e., without storing a large table)?
  
  ➔ Arithmetic coding
  
  ➔ First: Shannon-Fano-Elias coding (idealized variant of arithmetic coding)
Basic Idea of Shannon-Fano-Elias Coding

**Special Block Code for** $N$ **symbols**

- Order all possible symbol sequences with $N$ symbols: $s_1, s_2, s_3, \cdots$
- Each symbol sequence $s_k$ is associated with a half-open interval $\mathcal{I}(s_k) = [L, L+W)$ of the cdf $F(s)$

$\implies$ Transmit any number $v$ inside the interval $\mathcal{I}(s_k)$ as binary fraction
### Unique Identification of Probability Intervals

#### Probability Intervals
- All half-open intervals $\mathcal{I}(s_k) \subset [0, 1)$ are disjoint by definition
- Each interval $\mathcal{I}(s_k) = [L, L+W)$ is characterized by
  - $\text{interval width: } W = F(s_k) - F(s_{k-1}) = P(S = s_k) = p(s_k)$
  - $\text{lower boundary: } L = F(s_{k-1}) = P(S < s_k) = \sum_{i<k} p(s_i)$

#### Identification of Intervals by Binary Fraction
- All real numbers $v \in [0, 1)$ belong to exactly one interval
- Represent number $v \in \mathcal{I}(s_k)$ as binary fraction with $K$ bits of precision

\[ v = (0.b_1b_2b_3\cdots b_K)_b = \sum_{i=1}^{K} b_i \cdot 2^{-i} = z \cdot 2^{-K} \quad (z \text{ is an integer}) \]

- $\text{codeword: } \text{Bit sequence } \{b_1, b_2, b_3, \cdots, b_K\}$
- Binary representation of integer $z$ with $K$ bits
How Many Bits for Identifying an Interval?

Required Number of Bits

- Distance between successive binary fractions of $K$ bits is $2^{-K}$
- For guaranteeing that a binary fraction of $K$ bits falls inside an interval $I(s_k)$ of width $W$, we require
  \[ 2^{-K} \leq W \]
  \[ K \geq -\log_2 W \]
- Hence, we choose
  \[ K = \lceil -\log_2 W \rceil = \lceil -\log_2 p(s_k) \rceil \]
How To Select Codeword?

Interval Representative (number \( v \in I \))

- Round up lower interval boundary \( L \) to next binary fraction of \( K \) bits

\[
I = [L, W] : \quad v = \lceil L \cdot 2^K \rceil \cdot 2^{-K} \quad \text{with} \quad K = \lceil - \log_2 W \rceil
\]

Codeword

- \( K \) fractional bits of interval representative \( v = (0.b_1b_2b_3 \cdots b_K)_b \)
- Binary representation \([b_1b_2 \cdots b_K] \) with \( K \) bits of integer number

\[
z = \lceil L \cdot 2^K \rceil = v \cdot 2^K \]
Shannon-Fano-Elias Encoding

given:  
- ordered set of sequences \( \{s_k\} \)
- associated pmf \( p_k = p(s_k) \)

**Codeword construction** for \( s_k \)

1. determine interval \( I = [L, L+W) \)
   \[
   W = p(s_k) \quad \text{and} \quad L = \sum_{i<k} p(s_i)
   \]

2. determine codeword length \( K \)
   \[
   K = \lceil -\log_2 W \rceil
   \]

3. determine representative integer \( z \)
   \[
   z = \lceil L \cdot 2^K \rceil
   \]

4. determine codeword
   \[
   \text{K-bit representation of integer } z
   \]

**Codeword:** binary representation of \( z \) with \( K \) bits

integer part: \( z = \lfloor L \cdot 2^K \rfloor \)

number of bits:
\[
K = \lceil -\log_2 W \rceil
\]

\( W = p(s_k) \)

\( L = \sum_{i<k} p(s_i) \)
Shannon-Fano-Elias Decoding

given:
• ordered set of sequences \( \{s_k\} \)
• associated pmf \( p_k = p(s_k) \)

Decode given codeword

1. read **codeword** \( \Rightarrow \) integer \( z \) of \( K \) bits

2. initialization:
   \[
   v = z \cdot 2^{-K} \\
   k = 1 \quad (message \ index) \\
   U_k = L(s_1) + W(s_1) = p(s_1)
   \]

3. if ( \( v < U_k \) )
   \( \Rightarrow \) output \( s_k \)  
   
   (decoded message)
   
   else
   \( \Rightarrow \) update:
   \[
   k = k + 1 \\
   U_k = U_{k-1} + p(s_k)
   \]

   \( \Rightarrow \) goto step 3

read **codeword**: binary representation of \( z \) with \( K \) bits

representative value:
\[
\nu = z \cdot 2^{-K}
\]

decoding process:
Compare \( \nu \) with upper interval boundaries \( U = L + W \) in increasing order

\[
U_k > \nu \\
U_{k-1} \leq \nu \\
\vdots \\
U_1 \leq \nu
\]

\[
U_k = \sum_{i \leq k} p(s_i)
\]

\( s_1 \ldots s_{k-1} s_k s_{k+1} \ldots \) sequences \( s \)

Average codeword length: $\bar{\ell} = 0.733$

Block Huffman code: $\bar{\ell} = 0.728$

$W_k = p_k$

$L_k = \sum_{i<k} p_i$

$K_k = \lceil -\log_2 W_k \rceil$

$z_k = \lceil L_k \cdot 2^{K_k} \rceil$

Worse than block Huffman code for same block size ($N = 3$)

**Code is not prefix-free!** Can be a problem (depends on application)!
Why Is The Code Not Prefix-Free?

- Encoder transmits codeword of $K$ bits, signaling the binary fraction $v \in \mathcal{I}$

$$v = (0.b_1 b_2 b_3 \cdots b_K)_b$$

- Decoder sees a modified binary fraction $v^*$ given by

$$v^* = (0.b_1 b_2 b_3 \cdots b_K b_{K+2} b_{K+3} \cdots)_b$$

where $\{b_{K+1} b_{K+2} \cdots\}$ are the bits of following codewords

→ Value $v^*$ seen by decoder can lay outside the interval $\mathcal{I}$
Prefix-Free Variant: How Can We Fix That?

→ Need to ensure that $v^* < L + W$

\[
\text{worst case : } v^* = v + \sum_{i=K+1}^{\infty} 2^{-i} < L + W
\]

\[
\text{sufficient : } v + 2^{-K} \leq L + W
\]

\[
v = \left\lfloor L \cdot 2^K \right\rfloor 2^{-K} : \quad \left\lfloor L \cdot 2^K \right\rfloor \cdot 2^{-K} + 2^{-K} \leq L + W
\]

\[
\left\lfloor x \right\rfloor < x + 1 : \quad (L \cdot 2^K + 1) \cdot 2^{-K} + 2^{-K} \leq L + W
\]

\[
L + 2 \cdot 2^{-K} \leq L + W
\]

\[
2^{1-K} \leq W
\]

→ need : $K \geq 1 - \log_2 W$

→ Unique decodability is guaranteed, if we choose

→ prefix-free : $K = \left\lfloor 1 - \log_2 W \right\rfloor$

→ Require one additional bit per codeword (i.e., per $N$ symbols)
Example: Prefix-Free Shannon-Fano-Elias Code

Repeated: Blocks of 3 Symbols for a Binary IID Source

→ Binary iid source with alphabet $\mathcal{A} = \{a, b\}$ and pmf $p = \{0.8, 0.2\}$

</table>

Worse than block Huffman code (several redundant bits)
Efficiency of Shannon-Fano-Elias Codes

Average Codeword Length

- Average codeword length $\bar{\ell}$ per symbol (for $N$-symbol messages $S$)

$$\bar{\ell} = \frac{E\left\{K(S)\right\}}{N} = \frac{E\left\{\left[A - \log_2 p_N(S)\right]\right\}}{N}$$

with $A = \begin{cases} 1 : \text{prefix-free} \\ 0 : \text{otherwise} \end{cases}$

Bounds on Average Codeword Length

- Using the inequality $x \leq \lceil x \rceil < x + 1$, we obtain

$$\frac{E\{-\log_2 p_N(S)\}}{N} + \frac{A}{N} \leq \bar{\ell} < \frac{E\{-\log_2 p_N(S)\}}{N} + \frac{1 + A}{N}$$

$$\frac{H_N(S)}{N} + \frac{A}{N} \leq \bar{\ell} < \frac{H_N(S)}{N} + \frac{1 + A}{N}$$

→ Non-prefix-free version ($A = 0$): Same bounds as for block Huffman coding

→ Both versions: Close to entropy rate for $N \gg 1$ (for typical sources)
Shannon-Fano-Elias Coding: Intermediate Results

**Shannon-Fano-Elias Code**
- Special block code (for given number of symbols $N$)
- Worse than block Huffman code of same size $N$
- Still close to entropy bound ($H_N/N$) for $N \gg 1$

> No need to store codeword table!

> Have to store $N$-th order joint pmf (or $N$-th order joint cdf)!

What is the advantage?

**Iterative Coding**
- Can define a suitable order for sequences of $N$ symbols
- Iterative calculation of interval boundaries
- Iterative codeword construction
Lexicographical Order

- Sorted alphabet $\mathcal{A} = \{a_1, a_2, a_3, \cdots\}$
- Two symbol sequences: $x < y$ iff
  $\exists n : \left( \forall k < n : x_k = y_k \right) \land \left( x_n < y_n \right)$

**Example:** $\mathcal{A} = \{a, b, c\}$

$N = 4$:

- $\overbrace{a\ a\ a\ a}$
- $\overbrace{a\ a\ a\ b}$
- $\overbrace{a\ a\ a\ c}$
- $\overbrace{a\ a\ b\ a}$
- $\overbrace{a\ a\ b\ b}$
- $\overbrace{a\ a\ b\ c}$
- $\overbrace{a\ a\ c\ a}$
- $\overbrace{a\ a\ c\ b}$
- $\overbrace{a\ a\ c\ c}$
- $\overbrace{a\ b\ a\ a}$
- $\overbrace{a\ b\ a\ b}$
- $\overbrace{a\ b\ a\ c}$
- $\overbrace{a\ b\ a\ c}$
- $\overbrace{a\ b\ a\ c}$

- $\overbrace{c\ b\ b\ b}$
- $\overbrace{c\ b\ b\ c}$
- $\overbrace{c\ b\ c\ a}$
- $\overbrace{c\ b\ c\ b}$
- $\overbrace{c\ b\ c\ c}$
- $\overbrace{c\ c\ a\ a}$
- $\overbrace{c\ c\ a\ b}$
- $\overbrace{c\ c\ a\ c}$
- $\overbrace{c\ c\ b\ a}$
- $\overbrace{c\ c\ b\ b}$
- $\overbrace{c\ c\ b\ c}$
- $\overbrace{c\ c\ c\ a}$
- $\overbrace{c\ c\ c\ b}$
- $\overbrace{c\ c\ c\ c}$

$W_0 = 1$

$L_0 = 0$

$\Rightarrow$ probability intervals are nested!
Iterative Interval Refinement

\[
\begin{align*}
W_0 &= 1 \\
L_0 &= 0 \\
W_n &= W_{n-1} \cdot p(s_n | \cdots) \\
L_n &= L_{n-1} + W_{n-1} \cdot c(s_n | \cdots)
\end{align*}
\]

\[
\begin{align*}
P(s_{n-1} = \cdots) &= W_{n-1} \\
P(s_{n-1} < \cdots) &= L_{n-1}
\end{align*}
\]

\[
\begin{align*}
W_n &= P(s^n = \cdots x) \\
&= P(s^{n-1} = \cdots) \cdot P(s_n = x | \cdots) \\
&= W_{n-1} \cdot p(x | \cdots)
\end{align*}
\]

\[
\begin{align*}
L_n &= P(s^n < \cdots x) \\
&= P(s^{n-1} < \cdots) + P(s^{n-1} = \cdots) \cdot P(s_n < x | \cdots) \\
&= L_{n-1} + W_{n-1} \cdot \sum_{\forall a < x} p(a | \cdots) \\
&= L_{n-1} + W_{n-1} \cdot c(x | \cdots)
\end{align*}
\]
Iterative Interval Refinement in Practice

Iterative Algorithm for Calculating Interval Boundaries

- Initialization: \( W_0 = 1 \)
  \( L_0 = 0 \)

- Iteration Step: \( W_n = W_{n-1} \cdot p(s_n | \cdots) \)
  \( L_n = L_{n-1} + W_{n-1} \cdot c(s_n | \cdots) \)
  
  \[ c(x | \cdots) = \sum_{\forall a < x} p(a | \cdots) \]

- Require \( N \)-th order conditional pmf instead of \( N \)-th order joint pmf
- Same amount of data! ➔ What is the advantage?

Iterative Refinement in Practice

- Conditional pmfs can be well approximated using simple models
  - IID model: \( p(s_n | s_{n-1}, \cdots) = p(s_n) \)
  - Markov model: \( p(s_n | s_{n-1}, \cdots) = p(s_n | s_{n-1}) \)
  - Simple function: \( p(s_n | s_{n-1}, \cdots) = p(s_n | f(s_{n-1}, \cdots)) \)
Iterative Encoding Algorithm

Given: Sequence $s = \{s_1, s_2, s_3, \cdots, s_N\}$ of $N$ symbols

1. Initialization of probability interval
   
   $W_0 = 1$ and $L_0 = 0$

2. Determine probability interval $[L_N, L_N + W_N)$:
   
   for $n = 1$ to $N$:
   
   $W_n = W_{n-1} \cdot p(s_n | \cdots)$
   
   $L_n = L_{n-1} + W_{n-1} \cdot c(s_n | \cdots)$

3. Determine codeword length and codeword value
   
   $K = \lceil -\log_2 W_N \rceil$ (for prefix-free variant: $K \to K + 1$)
   
   $z = \lfloor L_N \cdot 2^K \rfloor$

4. Transmit codeword: Binary representation of $z$ with $K$ bits
Iterative Encoding Example: IID Source

L_{n+1} = L_n + W_n \cdot c(s_n)
\]

Heiko Schwarz (Freie Universität Berlin) — Data Compression: Universal Codes, V2V Codes, and Shannon-Fano-Elias Codes
Iterative Decoding Algorithm

Given:
- Bitstream \( \{b_1, b_2, b_3, \ldots, b_M\} \) of \( M \geq K \) bits
- Number \( N \) of symbols to be decoded

1. Determine interval representative:
   \[ v = (0.b_1 b_2 b_3 \cdots b_M)_{b} = z \cdot 2^{-M} \]

2. Initialization of probability interval:
   \( W_0 = 1 \) and \( L_0 = 0 \)

3. For \( n = 1 \) to \( N \):
   - \( \text{iterative decoding} \)
     a. Initialization of upper interval boundary \( U_1 \) for first symbol \( a_1 \) of sorted alphabet
        \[ k = 1, \quad U_k = L_{n-1} + W_{n-1} \cdot p(a_k | \cdots) \]
     b. While \( v \geq U_k \), update upper boundary for next alphabet symbol
        \[ k = k + 1, \quad U_k = U_{k-1} + W_{n-1} \cdot p(a_k | \cdots) \]
     c. Output symbol \( a_k \) and update probability interval
        \[ W_n = W_{n-1} \cdot p(a_k | \cdots) \]
        \[ L_n = U_k - W_n \]
Iterative Decoding Example: IID Source

\[ L_{n+1} = L_n + W_n \cdot c(.) \]

\[ W_{n+1} = W_n \cdot p(.) \]

\[
\begin{array}{c|cccccc}

\]

\[ \nu = \frac{452}{512} \quad b = "111000100" \quad \Rightarrow \quad s = "BANANA" \]
Summary of Lecture: Universal, V2V, Shannon-Fano-Elias Codes

Universal Codes
- Follow certain structure  ➔  No codeword table required
- Examples for coding non-negative integers: Unary code, Rice codes, Exp-Golomb codes

V2V Codes
- Mapping of variable-length symbol sequences to codewords
  ➔  Typically higher efficiency than block Huffman codes with same number of codewords

Shannon-Fano-Elias Codes
- Sub-optimal block codes (still close to entropy rate for $N \gg 1$)
- No codeword table required
  ➔  Iterative encoding and decoding procedure
  ➔  Precursor of arithmetic coding (used in most modern codec’s)
Exercise 1: V2V Codes for Black and White Document Scans (Part 1/2)

Analyze a structured V2V code for coding 300dpi black and white document scans

1. Write a program that reads all binary samples of a document scan into an array of bits (e.g., of type `vector<bool>` if you use C++)

The original document files are coded in the PBM format, which is a raw data format (see description on the right hand side).

The following files (found on the course web site) should be used as examples:

- “paper300dpi-page00.pbm”
- “paper300dpi-page01.pbm”
- “paper300dpi-page02.pbm”
- “paper300dpi-page03.pbm”

**structure of “pbm” files:**

```
P4 // ascii (fixed)
width height // ascii
<binary data> // binary
```

**binary data:**

- samples in raster-scan order (line by line)
- each sample is represented by one bit
  - bit 0 → white sample
  - bit 1 → black sample
- 8 bits are packet in one byte, where the first sample in scan order is placed in the most significant bit
- the first byte of the binary data contains the first 8 bits in scan order, etc.
Exercise 1: V2V Codes for Black and White Document Scans (Part 2/2)

2. Extend your program as follows:
   Experimentally determine the probabilities for the symbol sequences of the two codes (block code and V2V code) shown on the right hand side.

3. Develop optimal codeword tables for both cases (using the Huffman algorithm).
   You can do it on paper or implement it.

4. Calculate the average codeword length (per binary sample) for both developed codes.
   Which code would yield a better compression efficiency?
Exercise 2: Audio Coding using Rice Codes

Investigate lossless audio coding with Rice codes. Use the example file “audioData.raw” (from the course website) for these investigations. The file consists of raw audio data in signed 8-bit format. That means, each byte of the file represents one sample and has to be interpreted as 8-bit signed integer.

1. Write an encoder and decoder for coding the audio data using Rice codes.
   - Each sample $x_n$ should be coded as: $\text{abs} \rightarrow \text{Rice code for abs}(x_n)$
     
     $\text{if}(\text{abs} > 0)$
     $\text{sign} \rightarrow \text{single bit indicating the sign}$

   - The Rice parameter should be given as input to the encoder and written at the beginning of the bitstream (e.g., using a fixed-length code of 8 bits or a unary code).

   - Check that the decoder decodes the file correctly.

   - Try different Rice parameters and measure the size of the generated bitstream.

2. (Optional) Try to improve your lossless audio codec by coding the audio samples using chunks of 1024 successive samples.
   - Determine the optimal Rice parameter for each chunk.

   - Code the Rice parameter at the beginning of each chunk.
Exercise 3: Iterative Shannon-Fano-Elias Coding

Given is an IID source with the alphabet $\mathcal{A} = \{ \text{E, R, F} \}$ and the pmf

<table>
<thead>
<tr>
<th>symbol</th>
<th>probability</th>
</tr>
</thead>
<tbody>
<tr>
<td>E</td>
<td>$\frac{5}{8}$</td>
</tr>
<tr>
<td>R</td>
<td>$\frac{2}{8}$</td>
</tr>
<tr>
<td>F</td>
<td>$\frac{1}{8}$</td>
</tr>
</tbody>
</table>

1. Construct the Shannon-Fano-Elias codeword for the message “REFEREE” using the iterative encoding algorithm.
   - Use the prefix-free variant (only important at the end).
   - Assume that the symbols in the alphabet are ordered as: E, R, F.

2. Verify that the original message can be correctly decoded from the codeword using the iterative decoding algorithm.

Feel free to implement the encoding and decoding (instead of doing it on paper).
